¹Laboratorio de Micología, Instituto de Biología, UNAM. Apartado Postal 70-233, México, D.F., 04510.

²Centro de Investigación en Alimentación y Desarrollo A.C., Apartado Postal 1735, Hermosillo, Sonora, 83000.

ABSTRACT

There are some publications on *Geastrum* from Mexico but not enough to integrate a monograph for the country. The present contribution lists the habitat and distribution of the species in Mexico and some outstanding aspects of their ecological relations. Scanning electron microscopy studies have been done to get more information on the fine structure of capillitium and spores of the Mexican specimens. The species reported herein are: *G. campestre*, *G. coronatum*, *G. fimbriatum*, *G. floriforme*, *G. fornicatum*, *G. javanicum*, *G. lageniforme*, *G. minimum*, *G. pectinatum*, *G. quadrifidum*, *G. saccatum*, *G. schweinitzii*, *G. triplex*, and *G. xerophilum*. Some aspects of their ethnomyiological importance taken from the literature are indicated.

Key words: *Geastrum*, Gasteromycetes, taxonomy, distribution, ecological notes.

RESUMEN

ESPECIES DE *GEASTRUM* (BASIDIOMYCOTINA: GEASTRACEAE) EN MÉXICO. Rev. Mex. Mic. 15: pp-pp (1999). Se indican las especies del género *Geastrum* que han sido registradas de México, así como algunos datos sobre su morfología, hábitat y distribución. Se describen las características de las esporas y del capilicio de las especies estudiadas con base en observaciones en el microscopio electrónico de barrido. Las especies consideradas son: *G. campestre*, *G. coronatum*, *G. fimbriatum*, *G. floriforme*, *G. fornicatum*, *G. javanicum*, *G. lageniforme*, *G. minimum*, *G. pectinatum*, *G. quadrifidum*, *G. saccatum*, *G. schweinitzii*, *G. triplex* y *G. xerophilum*. Se indican algunos aspectos sobre su importancia etnomicológica con base en una revisión bibliográfica.

Palabras clave: *Geastrum*, Gasteromycetes, taxonomía, distribución, notas ecológicas.

Introduction

There are important publications dealing with the species of *Geastrum* from many regions of the world, most of them useful for the identification of the Mexican species. Some of these are: Lloyd (1902, 1907), Longnecker (1927), Coker & Couch (1928), Cunningham (1942), Long & Stouffer (1948), Smith (1951), Cejp *et al.* (1958), Dissing & Lange (1961), Dissing (1962a,b), Ponce de León (1968), and Sunhede (1989). The species of *Geastrum* have been cited frequently in publications on the macromycetes of Mexico (Herrera, 1964; Salcedo & Herrera, 1966; Guzmán & Herrera, 1969, 1973; Pérez-Silva, 1974; Guzmán, 1977; Frutis & Guzmán, 1983; Martínez-Alfaro *et al.*, 1983; Acosta & Guzmán, 1984; Esqueda-Valle *et al.*, 1990, 1995; Ochoa-Morales, 1993; Pérez-Silva *et al.*, 1994). Even though there are few papers treating specially on the genus in this country (Herrera, 1957; Pérez-Silva, 1974). Remarks on the taxonomic characters are indicated in the

present paper specially for the spores and capillitium observed under the SEM. The importance of the genus is briefly discussed. Data on distribution of the species of *Geastrum* in Mexico are included. The species are in alphabetical order and a key to them is presented.

Materials and methods

Dry specimens from several Mexican herbaria and fresh specimens were studied under conventional optical microscopes (OM), and under the scanning electron microscope (SEM). Fragments of gleba on the surface of adhesive tape strips were disposed on special cylinders or sample holders covered under vacuum conditions with a 300 Å gold or aluminium layer using an ionizer Jeol FG-100, and observed under a Jeol JSH-35C SEM.

Key to the mexican species of *Gastrum*

Species description

Gastrum campestre (Morg.) Stanek, Fl., CSR, B-1: 463, 1958.

= *Geaster campestris* Morg. Amer. Nat. 21: 1026, 1887.

= *G. berkeleyi* Massee, Am. Bot. 4: 79, 1891.

= *G. pseudomammosum* Henn., Hedwigia 39: 54, 1900.

= *G. asper* Lloyd, Geastrae 18, 1902.

Fig. 1.

Macroscopic characters: Gastrocarp 1.5-4 cm wide when expanded. Exoperidium splitting about the middle into 6-12 hygroscopic, equal, acute rays, spreading out when wet, involute or sometimes revolute when dry, frequently folding over or under the endoperidial sac. Mycelial layer persistent, covered with debris and umbilicate at the base. Fibrous layer thin, adherent, gray or whitish. Fleshy layer yellowish gray to dark brown, in old specimens frequently rimose, but continuous in young

specimens. Endoperidial sac subglobose or depressed globose, subsessile to short-pedicellate, whitish gray or yellowish brown, covered with minute and dense wart-like granules. Peristome small, conical, concolorous or often dark brown, acute or blunt, strongly sulcate in a well delimited zone. Gleba dark brown. Columella small, subspherical, persistent.

Microscopic characters: Spores globose, verrucose, 5-7 µm in diameter including ornamentation, chestnut brown, often with a stump of pedicel (Fig. 1). Capillitium threads 3-5 µm diam, pale yellowish, with thick walls, frequently tapering at the ends, scarcely branched, some of them flexuous.

Habit and habitat: Gregarious, in sandy soil with cow dung under *Prosopis juliflora*, and in tropical forest.

Distribution: Sonora: Hermosillo municipality, in a urban zone near a cattle barn, leg. M. Esqueda & R.E. Villegas (07.V.1993) CESUES 1580. San Javier municipality, Km 137 Hermosillo - Yécora road, leg.

Gastrum coronatum Pers. *Syn. Meth. Fung.*, p.
132, 1801

= *G. multifidum* DC. *Fl. Fr.* 2: 267, 1805.

= *G. limbatum* Fr. *Syst. Mycol.* 3: 15-16, 1829.

= *G. atratum* Smarda, *Ces. Mykol.* 1: 71, 1947 (as
Geaster).
Fig. 2.

Macroscopic characters: Gastrocarp 2.5-8 cm wide when expanded, mostly 3-5 cm. Exoperidium splitting to about the middle into 4-10 acute, unequal rays, not hygroscopic but sometimes involute or partially revolute. Mycelial layer incrusted with debris, eventually loosening from the fibrous layer remaining as a thin cup. Fibrous layer grayish white, papery. Fleshy layer whitish gray to dark brown, 3-4 mm thick. Endoperidial sac stalked, globose, subglobose, ovoid or subellipsoid, papyraceous, with a marginal rim or collar at the base (apophysis), dark brown or purplish, with a hoary sheen on the surface due to many glistening minute particles. Peristome flat or conical, more or less distinctly outlined by a groove paler than the remainder of the endoperidium. Gleba grayish to dark brown. Columella of varying shape, generally columnar, persistent or almost obsolete.

Microscopic characters: Spores spherical, 4-5 µm diam.; hilar appendage conspicuous, hollow, with radial ridges which are mixed with the ornamentation of the spore in the basal region. Episporium with or without coalescent processes 1 µm high; the surface between these processes with some bridge like connections and several granulations and scales, providing a pulverulent surface (Fig. 2). Capillitrial hyphae 4-5 µm wide, smooth but often with remains of gleba.

Habit and habitat: Solitary, terrestrial, in mixed and tropical forest, and grasslands. 120-2900 m alt.

= *G. infrequens* Lloyd, *Myc. Writ.* 2: 263, 1906.

Fig. 3.

Macroscopic characters: Gastrocarp 2-5 cm wide when expanded, mostly 3-4 cm. Exoperidium more or less saccate, sometimes plane or arched at the base, splitting to about the middle into 6-10 pointed, unequal rays, not hygroscopic, but frequently involute and sometimes partially revolute. Mycelial layer felted, whitish or yellowish, naked or incrusted by debris, persisting or flaking off. Fibrous layer thin, light brown, smooth. Fleshy layer whitish at first, dark brown with age, about 1-3 mm thick, tending to become rimose. Endoperidial sac sessile, globose or subglobose, 1-3.5 cm diameter, tan to dark brown, or blackish gray, apparently smooth but covered by protruding hyphae as seen under a lens. Peristome indeterminate, sometimes lighter than the surrounding endoperidial surface, finely fibrillose, flat or

mammiform, with fimbriate margin. Gleba fuscous brown. Columella club-shaped, evident or inconspicuous.

Microscopic characters: Spores in mass brown, 3.5-4.5 μm including ornamentation, under SEM episporule 1.4 μm thick, with claviform processes which are capitate with flat tips, coalescent in small groups of two or more forming irregular ridges, the processes near the hilar appendage more or less confluent and clustering in a rosette (Fig. 3). Capillitium hyphae 1.5-2 μm wide, wall more or less rugose, with or without remains of gleba. In young spores the processes of the ornamentation are very close and often with narrow bridges among them. These processes are loose in mature spores.

Habit and habitat: Solitary or gregarious, on soil in forest of *Quercus*, *Pinus-Quercus*, *Abies religiosa*-*Pseudotsuga* and *Pinus hartwegii*.

Fig. 4.

Macroscopic characters: Gastrocarp 1-5 cm wide when expanded mostly 2-4 cm. Exoperidium sacculiform or plane, umbilicate or rounded at the

base, splitting to the middle or a little more into 5-10 narrow, acute, strongly hygroscopic rays which are revolute over the endoperidial sac. Mycelial layer thin, whitish, with adhering sand debris, but soon disappearing. Fibrous layer smooth, grayish brown. Fleshy layer thin, persistent, very hard and cracked in age whitish to grayish, dark brown or blackish. Endoperidial sac sessile, globose, subglobose or depressed globose, almost smooth or somewhat furfuraceous. Peristome not distinctly delimited, more or less fibrillose, the mouth naked, slightly fimbriate when old. Gleba umber or brown. Columella of varying shape, generally columnar, persistent or obsolete.

Microscopic characters: Spores spherical, 4.5-5.5 μm diam. including ornamentation, which is composed of truncate or conical warts around 0.5 μm high, some of them coalescent at the tips, as observed under SEM. Capillitrial hyphae thick-walled, smooth, but often with granular remnants of the gleba, 2-4 μm wide (Fig. 4).

Habit and habitat: Solitary or in small groups, in urban areas or semiarid mountains, under *Schinus molle*, grasslands, and *Yucca filifera* (Izote).

Distribution: Distrito Federal: Cerro de la Estrella, Iztapalapa, leg. T. Herrera & O. Sánchez (12.VIII.1956) MEXU 1052. **Sonora:** Altar municipality, 4 Km NE Altar, leg. H. Fig. 5.

Macroscopic characters: Gastrocarp 3-10 cm high, 4-8 cm across when expanded, fornicate at maturity. Exoperidium splitting very deeply mostly into 4 rays, but sometimes 5-6 rays are formed, the rays narrow

or broad, not hygroscopic, thick and rigid with the tips attached to the margin of the mycelial cup. Mycelial layer thick, whitish or light brown, persisting in the ground as a cup. Fibrous layer thin, turning brown in old specimens when the fleshy layer has peeled off. Fleshy layer thick, dark brown and hard in age, but remaining only partially on the fibrous layer. Endoperidial sac stalked, globose, depressed globose or urceolate, 1-3 cm across, at the base often with a distinct apophysis, light gray to blackish brown, when young covered by protruding hyphae and whitish minute crystals which generally disappear with age. Peristome not well delimited, but often fibrillose or silky and lighter than the rest of the endoperidium, the mouth is frequently white, fibrillose to lacerate, even mammiform or shortly tubular. Gleba dark brown. Columella well developed or inevident, when present several-shaped, from columnar to conical, rounded or club shaped.

Microscopic characters: Spores globose, 3.5-5 μm diam., sculptured with columnar processes 0.5 μm long, scattered on the surface, leaving free areas 0.3 μm wide. The spines of immature spores are confluent. Hilar appendage 0.6 μm diam. x 0.25 μm long (Fig. 5). Capillitrial hyphae thick walled, with the surface slightly rugose often partially covered by remnants of gleba, 2-6 μm wide.

Habit and habitat: Gregarious, terrestrial, in tropical forest, urban zone under *Schinus molle*, and in mezquital or grassland.

Distribution: Hidalgo: Km 5 SW of Huichapan, leg. J. Acosta w/n (15.IV.1978) ENCB. **Sonora:** Bacoachi municipality, Km 146 Mazocahui - Cananea road, leg. M. Esqueda & J. Fig. 6.

Macroscopic characters: Gastrocarp up to 6-8 cm wide when expanded. Exoperidium with a prominent umbilical scar at the base, splitting to about the middle into 4-8 not hygroscopic, flat, reflexed or revolute, and pointed rays. Mycelial layer thick, velvety or tomentose, easily splitting from the fibrous layer which remains adhered to the thin fleshy layer, the latter cream-colored or light brown when fresh, later becoming darker and rimose. Endoperidial sac sessile, globose or subglobose, papyraceous, light gray or brown, smooth or minutely tomentose. Peristome conical, fibrillose, light gray or brown. Gleba dark brown. Columella generally clavate, persistent or becoming obsolete.

Microscopic characters: Spores spherical, 3-4 μm diam.; episporium with blunt columnar processes, 0.3-0.4 μm wide \times 0.5 μm high; hilar appendage short, surrounded by spines which are \pm confluent in immature spores (Fig. 6). Capillitrial hyphae 2-2.5 μm diam.; surface rough with remains of gleba.

Habit and habitat: In forest of *Abies religiosa* and *Pinus* sp. from 2,700 to 3,150 m alt.

***Geastrum lageniforme* Vitt. Monogr. Lycoperd., p. 16, 1842.**

= *G. capense* Thümen. **Mycotheca Universalis**, No 715, 1877 (as *Geaster*). Fig. 7.

Macroscopic characters: Gastrocarp 2-7 cm wide when expanded, mostly 3-5 cm; unexpanded onion shaped or lageniform. Exoperidium not hygroscopic, splitting deeply into 5-10 often recurved rays, generally with long and slender tips, but the base remains saccate, arched or plane. Mycelial layer persistent, yellowish brown or whitish, smooth, longitudinally cracked on the rays. Fibrous layer thin, papery, grayish white. Fleshy layer light brown to dark brown or grayish, in age partially peeling off, 1-2 mm thick. Endoperidial sac sessile, globose or subglobose, 1-2 cm diam., smooth, light brown to dark brown or grayish. Peristome well delimited, sometimes almost flat or columnar, generally conical or mammiform, delicately fibrillose, often lighter than the endoperidial surface. Gleba yellow brown to dark brown. Columella generally club-shaped.

Microscopic characters: Spores globose, 3-4 μm diam. including ornamentation which is conformed by columnar processes with free tips, \pm convex, leaving free ornamented areas between them (Fig. 7). The immature spores have coalescent columns. The surface of capillitrial hyphae with remains of

gleba, sometimes devoid of them; 2.5-3 µm wide.

Habit and habitat: In mixed forest with *Abies religiosa*, *Pinus* sp., *Pinus-Quercus*, *Quercus* spp., and in coffee plantations.

Fig. 8.

Macroscopic characters: Gastrocarp 1-4 cm wide when expanded. Exoperidium not hygroscopic,

splitting to about the middle into 5-9 acute, subequal rays which often become recurved or remain in both horizontal and vertical positions. Mycelial layer whitish brown, persistent, attached to the fibrous layer or loosening as a cup in the substratum. Fibrous layer very thin, yellowish white or grayish. Fleshy layer white, pale yellow or dark brown, in age rimose, partially peeling off, 1-2 mm thick. Endoperidial sac with a short pedicel, globose, subglobose, ovate or pear-shaped, 0.5-1 cm diam., grayish brown, generally with apophyses, smooth or minutely granulose by the presence of white crystals. Peristome well delimited, subconical, bordered by a ring, concolorous with the endoperidial surface but often darker or lighter, delicately fibrillose. Gleba ferruginose to dark brown. Columella cylindrical or club shaped, small or obsolete.

Microscopic characters: Spores in mass brown, slightly equinulated; under SEM episporium with columnar processes, 0.7 x 0.9 µm diam., radially distributed from the basal side, with a granular surface between columns; hilar appendage inconspicuous, short, 0.75 µm wide (Fig. 8). Capillitium smooth often with remains of gleba, 1.5 - 1.8 µm diam.

Habit and habitat: Solitary, terrestrial, in mixed forest.

Fig. 9.

Macroscopic characters: Gastrocarp 2-10 cm wide when expanded, mostly 4-8 cm. Exoperidium not hygroscopic, splitting into 6-10 subequal, acute, expanded, incurved or recurved rays, with the central region convex above elevating the endoperidial sac. Mycelial layer persistent, well developed, strongly encrusted with debris. Fibrous layer very thin, whitish to brown or gray. Fleshy layer thin to about 1 cm thick, not rimose, grayish white to brown. Endoperidial sac globose, subglobose, depressed globose or urceolate, 1-3 cm diam., gray or brown, with a prominent slender stalk up to 1 cm long which frequently continues into a prominent often plicate or striate apophysis. Peristome generally broad conical or long and slender conical, plicate and strongly sulcate, pale to dark brown, well or indistinctly delimited from the surrounding endoperidial surface. Gleba chocolate brown. Columella well developed or rudimentary.

Microscopic characters: Spores in mass brown, finely echinulate; under SEM columnar processes can be observed, up to 0.5 μm high, with granular surface between them, radially distributed from the hilar appendage, some of the columns are confluent (Fig. 9). Pedicels very short, 1 μm wide. Capillitrial hyphae 3.5 μm wide, with sculptured surface and remains of gleba.

Habit and habitat: Solitary or gregarious, terrestrial, under *Prosopis juliflora*, *Lophocereus schottii*, *Schinus molle*, *Pinus*, *Abies* and *Juniperus* forests.

Geastrum quadrifidum Pers. *Syn. Meth. Fung.*, p. 133.

= *Lycoperdon coronatum* Scopoli. *Flora Carniolica ed. 2, II:* 490, 1772.

Fig. 10.

Macroscopic characters: Gastrocarp small to medium or large sized, 4-7 cm high, 2-8 cm wide when expanded, splitting to beyond the middle into 4-5 rays. Exoperidium not hygroscopic, typically fornicate, with the mycelial layer whitish remaining as a conspicuous cup which holds the tips of the rays at the border, strongly encrusted with debris. Fibrous layer thin, grayish white, remaining attached to the fleshy layer which is pale brown at first, dark brown and partially peeled off in old specimens. Endoperidial sac subglobose, depressed or urceolate, 0.5-1.5 cm diam., light gray to dark brown, pruinose in young specimens, smooth in age, short stalked, usually with an apophysis above the stalk which is 1-3 mm high. Peristome well delimited, conical, mammiform or tubular, silky fibrillose, concolorous or lighter than the endoperidial surface. Gleba ferruginous or chocolate brown. Columella well developed or rudimentary.

Microscopic characters: Spores in mass brown, 4 μm diam. including ornamentation; under SEM

conical processes can be observed, up to 0.5 µm high; the surface between columns rugose in immature spores; verrucae confluent forming ridges; hilar appendage short (Fig. 10). Capillitrial hyphae 1-2 µm wide, with sculptured surface and remains of gleba.

Habit and habitat: Terrestrial, in grasslands.

Distribution: **Chiapas:** Km 18 Ocozocuautla - Malpaso road, leg. C. Gallegos 27 (02.IX.1979) FCME 10729. **Sonora:** Arizpe municipality, Km 122 Mazocahui - Cananea road, leg. M. Esqueda & J. Gastrum saccatum (Fr.) Fischer, Nat. Pflanz. 2(7): 73, 1933

= *Geaster saccatus* Fr. Syst. Myc. 3: 16, 1829.

Fig. 11.

Macroscopic characters: Gastrocarp 2-5 cm wide when expanded. Exoperidium generally saccate, splitting to beyond the middle into 6-8 acute, subequal rays, not hygroscopic, expanded, involute, reflexed or revolute. Mycelial layer thick, free of debris, sometimes with longitudinal cracks, peeling off or persisting in age. Fibrous layer thin, grayish white. Fleshy layer thick, whitish brown in age, peeling off or persistent in old specimens. Endoperidial sac sessile, globose or subglobose, 0.6-2.5 cm, papyraceous, almost smooth, whitish or light brown. Peristome generally well delimited, mammiform or conical, in some specimens almost flat. Gleba pale to dark brown. Columella indistinct or well developed, rounded, claviform or cylindrical, light colored.

Microscopic characters: Spores spherical, 3-4 µm in diameter including the ornamentation, which consists of columnar processes 0.5-0.8 x 0.5 µm, some of them confluent when young; hilar appendage short, 0.3 µm long x 0.5-0.7 µm in diam (Fig. 11). Capillitrial hyphae 1.5-3.0 µm wide, with the surface smooth or ornamented and generally with some remains of gleba.

Habit and habitat: Hypogeous early in development, emerging after development, growing in soil from tropical forest to mixed coniferous forest, solitary or gregarious. This is the most commonly found species in autumn, 1780-3000 alt.

Fig. 12.

Macroscopic characters: Gastrocarp 1.0-2.2 cm wide when expanded. Exoperidium saccate, splitting to about the middle into 6-7 not hygroscopic rays which are straight and upright rather than reflexed or inflexed. Mycelial layer thick, whitish, light yellow or brown, tomentose. Fibrous layer tightly adhering

to the fleshy layer which is thin, dark brown, persistent, often cracking in aged specimens. Endoperidial sac sessile, 0.5-1.0 cm thick, globose or subglobose, grayish brown or whitish gray, smooth or delicately felted. Peristome more or less conical, fimbriate, not sulcate, with a well delimited ring. Gleba light to dark brown. Columella generally not well developed.

Microscopic characters: Spores spherical, with prominent projections confluent in small groups and with many tiny granules among them (Fig. 12). Capillitium flexuose, 1.25 μm diam., ornamented with numerous scales.

Habit and habitat: Gregarious or caespitose on wood fragments in tropical forests.

Fig. 13.

Macroscopic characters: Gastrocarp up to 5-12 cm wide when expanded. Exoperidium splitting to about the middle into 4-9, usually 5-7, not hygroscopic, equal or subequal, acuminate rays which are flat, convex, revolute or often involute under the spore sac. Mycelial layer persistent, adhering small amount of debris, often cracking radially into light brown or yellowish strips, with a central umbilical scar. Fibrous layer thin, firmly adhered to the fleshy layer which is thick, whitish, yellowish gray or brown,

generally splitting around the base of the endoperidial sac into a typical cup or collar. Endoperidial sac sessile, globose or subglobose, 2-5 cm across, smooth, pale gray to brown. Peristome conical or mammiform, well delimited by a paler radially fibrillose area. Gleba dark brown in mature specimens. Columella generally well developed, subglobose or club-shaped.

Microscopic characters: Spores brown in mass, uniguttulate; as seen under SEM, ornamented with columnar processes, 0.5 μm high x 0.3 μm wide, connected by bridges; spines frequently confluent in groups of 2 or 3 (Fig. 13). Capillitium with sculptured surface, 1.5 - 2 μm wide.

Habit and habitat: Solitary or gregarious on the ground in tropical forest at 50 m alt., or more frequently found under conifer and mixed woods, 800-3200 m alt., especially in autumn.

Fig. 14.

Macroscopic characters: Gastrocarp 1-4 cm wide when expanded, with a prominent basal mycelial cord. Exoperidium splitting to about the middle into 8-10 not hygroscopic, unequal, pliable, subacute or truncate rays becoming involute around the endoperidial sac. Mycelial layer adnate, thin, covered by persistent sand grains, with a big umbilical scar at the base. Fibrous layer thin, adherent. Fleshy layer yellowish white or brown, eventually rimose. Endoperidial sac subsessile or with a short pedicel, depressed globose, 1-2 cm across, light brown, yellowish gray or whitish, minutely furfuraceous. Peristome concolorous, small, conic, unequally sulcate, without a surrounding groove. Gleba light or dark brown. Columella cylindrical, persistent.

Microscopic characters: Spores globose to slightly elliptical, 4-5 µm diam., coarsely verrucose under light microscope; under SEM dentate-conical verrucose spores can be observed; pedicels very short, up to 0.5 µm long, hollow (Fig. 14). Capillitium stout or flexuose, 2-3.5 µm diam., smooth, frequently with remains of gleba.

Habit and habitat: Solitary or in small groups, in open sandy areas of semi-arid locations with *Larrea tridentata*, *Fouquieria* sp. and *Cercidium* sp.; in *Quercus* forest, and under the shadow of *Olneya tesota*.

Distribution: Morelos: Tepetlixca municipality, Amecameca-Cuautla road, near Tepetlixca, leg. G. Guzmán 12072, (23.VI.1975) ENCB. Sonora: Hermosillo municipality, Hermosillo-Bahía de Kino

Discussion

The identification of the genus *Gastrum* is easy, but its determination and nomenclature at species level is often difficult and the separation between closely related taxa is not always easy. This is the case of *G. campestre* (Morg.) Stanek with the endoperidial sac pedicelled, and *G. drummondii* (Berk.) Cunn. with the endoperidial sac sessile. The intermediate forms are so many that these closely related taxa can not be always sharply separated. This situation can explain the long list of synonyms of some species and the change of the valid names, even of well known species such as *G. triplex* (Jungh.) Fisch. and *G. velutinum* (Morg.) Fisch. which are considered by some authors as conspecific with *G. indicum* (Koltz.) Rauschert and *G. javanicum* (Lév.) Ponce, respectively (Ponce de León, 1968). A world monograph of the genus is needed to avoid such confusions, considering new taxonomic approaches such as the cladistic, and including developmental culture, comparative molecular biology and SEM characters. This task will probably take a long time, meanwhile, small taxonomic contributions, as the present paper should be considered, as useful to increase the knowledge of the genus. *Gastrum* is a widely distributed genus in Mexico, often well represented in wet forests, but also frequent in dry regions. Several species such as *G. campestre* (Morg.) Stanek, *G. forniciatum* (Hud.) Hook., *G. minimum* Schw., *G. pectinatum* Pers., *G. saccatum* (Fr.) Fischer were found in urban zones. The genus includes species which possibly form mycorrhizae such as *G. triplex* and *G. quadrifidum* (Garza-Ocañas, 1986) although their importance in nature is not well known. This could be the basis for further studies. On the other hand, Kreisel (1969) considered that all the Geastraceae are saprophytes.

The species of *Gastrum* are not edible and there are few reports on their uses. Mata (1987) provided information about the employment of *G. triplex* against diarrhea, asthma, "evil eye" ("mal de ojo"), and to dry the navel of the newborn. Guzmán (1994a,b) reports the same uses for *G. saccatum* and

other related species such as *G. fimbriatum* which also are used to cure wounds by applying the apical part of the toadstool.

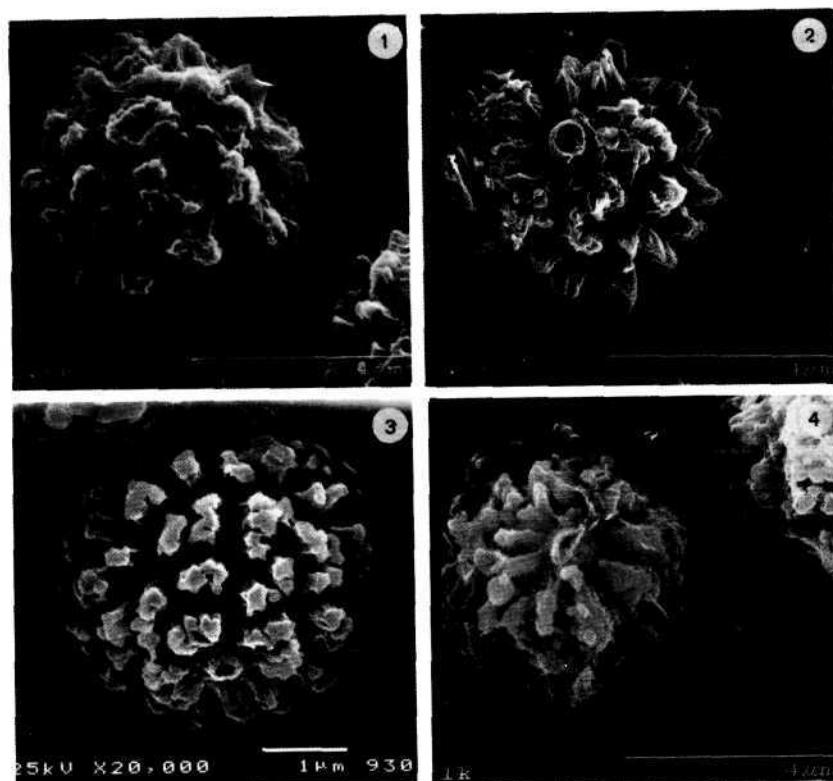

Acknowledgments

The authors acknowledge the financial support of the DGAPA project IN2038951, IN203895 (UNAM), and the SNI grants to E. Pérez-Silva and T. Herrera. The help of Jacqueline Cañetas, Pedro Mexia (Instituto de Física), Margarita Reyes (Instituto de Geología), and Sara Fuentes (Instituto de Biología) was very important in taking SEM photomicrographs. We are very grateful to them and also to Felipe Villegas (IB, UNAM), all from UNAM, for the valuable technical assistance. We also thank the curators of the herbaria CESUES, ENCB, FCME and MEXU for the loan of specimens of *Geastrum*. The critical revision of the paper by F. D. Calonge (Real Jardín Botánico de Madrid, España), and F. Chiang (IBUNAM); the comments of J. Cifuentes (Facultad de Ciencias, UNAM) is also appreciated.
